

`\shiftOttavaBracket`

NOTE: This whitepaper is not affiliated with nor validated by the GNU LilyPond project. It is not a substitute for official documentation. Information within is based on observed behavior of the program and might not align with the intended design. For reference, the version of LilyPond used was 2.19.83.

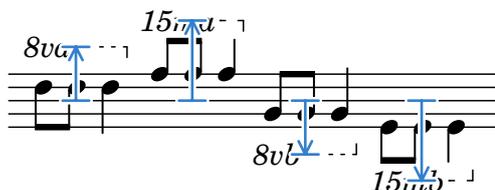

Overview

We would like a method for shifting an `OttavaBracket` away from its associated staff by a specified distance while preserving as much of the automatic collision avoidance behavior.

There are several obstacles to overcome. An `OttavaBracket`'s final vertical position relative to the staff is not determined by any single grob property. Shifting the bracket will require modifying multiple properties, some of which will have side-effects that must be compensated.

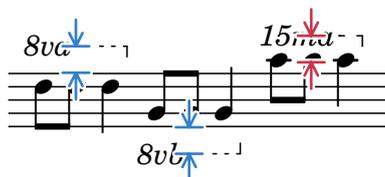

Y-offset

The `Y-offset` property is the distance, in staff spaces, between the reference points of an object and its parent. The reference point of an `OttavaBracket` aligns with the horizontal segment of its bracket symbol. The parent of an `OttavaBracket` is the `VerticalAxisGroup`, whose reference point coincides with the middle of the `StaffSymbol`.

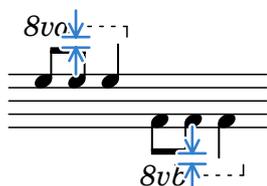

By default, the `OttavaBracket` does not specify a fixed value for `Y-offset` but rather uses a procedure to compute it. This procedure considers the position of some grobs, including `NoteHeads` and `Stems`, to determine where the bracket should be placed. Several associated properties are consulted.

The `staff-padding` property specifies the *minimum* distance between an `OttavaBracket`'s reference point and the nearest extent of the associated `StaffSymbol`. Note the presence of nearby grobs may result in the `OttavaBracket` being further away than this amount, as shown in the last scenario below.

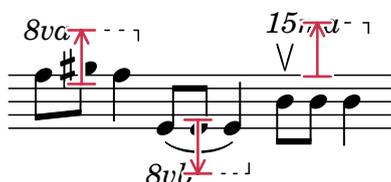

The `padding` property specifies the *minimum* distance between the `OttavaBracket` and neighboring grobs.

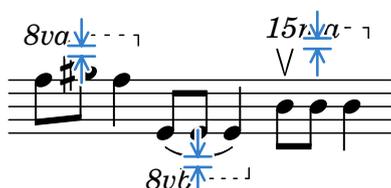

The default procedure for computing an `OttavaBracket`'s Y-offset does not factor in all grobs. Instead, `Accidentals`, `Slurs`, and `Scripts` are among those that are considered in a later round of processing. Should the value of Y-offset be too small, the bracket will be offset accordingly to avoid collisions.

In the examples below, the arrow being overlaid visualizes only the computed value of Y-offset. Its base *should* align with the middle of the `StaffSymbol`; however, these `OttavaBrackets` were moved.

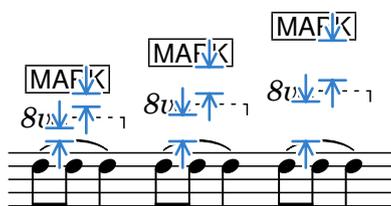

outside-staff-padding

The `outside-staff-padding` property, similar to the `padding` property, is consulted for shifting an `OttavaBracket` to avoid being too close to other grobs that are outside the staff.

It is important to note that `outside-staff-padding` applies to both sides of an `OttavaBracket`, affecting the spacing with grobs on the side opposite to the `StaffSymbol`, such as `RehearsalMarks`. For each example below, `outside-staff-padding` is being increased by one staff space.

extra-offset

Unlike the properties previously discussed, `extra-offset` is only applied after all layout logic has been performed. It represents an arbitrary shift in position that does not account for potential collisions. As shown below, `extra-offset` is a two-dimensional value; though we will only be interested in vertical adjustments.

First Attempt

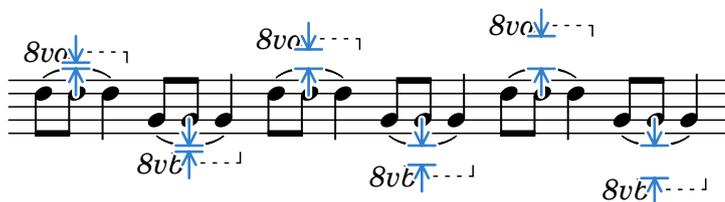

The simplest way to shift our `OttavaBracket` would be to `\offset` the `outside-staff-padding` property. Unfortunately, `OttavaBracket` does not have a base value that `\offset` can build upon. We can work around this issue by noting that, internally, the value 0.46 is used as the default `outside-staff-padding`. Instead of `\offsetting` the property, we will `\override` it after manually computing the value.

```

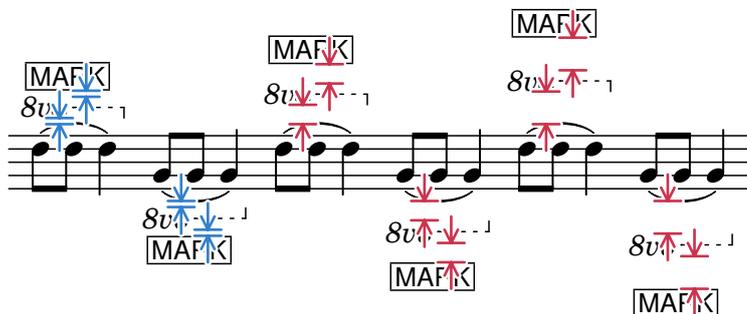

shiftOttavaBracket =
#(define-music-function
  (amount) (number?)
  #{
    \override Staff.OttavaBracket
      .outside-staff-padding = #(+ 0.46 amount)
  })

```

NOTE: For the remainder of the whitepaper, the examples will be testing with no shift, a shift of one staff space, and a shift of two staff spaces.

Initial testing seems promising, however we need to remember that the `outside-staff-padding` property affects spacing on both sides of the `OttavaBracket`. Let us add in some `RehearsalMarks` to see the impact of `\shiftOttavaBracket`.

The `RehearsalMarks` are moving by *twice* the amount we requested the `OttavaBracket` to move. This is because the extra amount added to `outside-staff-padding` exists on both sides of the bracket. Since we cannot selectively apply our extra padding to just one side, we will need a clever trick.

The first thing to recognize is that we should only be adding *half* of the requested amount to `outside-staff-padding`. This ensures that a grob like `RehearsalMark` will be moved the correct distance. However, doing this means the `OttavaBracket` only moves by half of what we need. This is where `extra-offset` can be used, as it will take care of moving our bracket the rest of the way.

On its own, `extra-offset` would not avoid collisions; but we have adjusted `outside-staff-padding` to ensure other grobs will already be moved sufficiently far to accommodate the additional nudging.

Second Attempt

In review, the method now involves applying half of the requested shift amount to outside-staff-padding and half to extra-offset. Note that care must be taken to ensure extra-offset is offsetting the proper direction.

```

shiftOttavaBracket =
#(define-music-function
  (amount) (number?)
  (let ((half (/ amount 2)))
    #{}
    \override Staff.OttavaBracket
      .outside-staff-padding = #(+ 0.46 half)
    \override Staff.OttavaBracket
      .extra-offset = #(lambda (grob)
        (let ((dir (ly:grob-property grob 'direction)))
          (cons 0 (* dir half))))))
  #{}
  ))

```

Testing shows improved results, where both the OttavaBracket and RehearsalMark appear to move as a single unit, maintaining their normal separation.

Thus far, we have only considered the situation when Y-offset is not large enough to avoid collision. In order for `\shiftOttavaBracket` to be useful, it must work also when the bracket is being influenced by Y-offset alone.

To see what happens with a larger Y-offset, let us increase the staff-padding property, which will in turn increase Y-offset. We will also remove the Slurs, so there is plenty of room between the bracket and the staff.

Since the OttavaBrackets are far enough away from any grobs, the increase of outside-staff-padding has no impact on the bracket itself. There is nothing to push against. With only extra-offset applying, the brackets have moved half of what we need.

However, we have a good idea for our next improvement. We should only need to `\offset` Y-offset by the remaining distance to get the OttavaBrackets in the correct spot.

Third Attempt

Since Y-offset is a signed value, we cannot simply `\offset` it by a fixed amount. This would only work for positive values. LilyPond provides `grob-transformer`, a handy construction that makes it easy to modify a base value with a custom procedure, even when that base value might be the result of another procedure.

```

shiftOttavaBracket =
#(define-music-function
  (amount) (number?)
  (let ((half (/ amount 2)))
    #{}
    \override Staff.OttavaBracket
      .Y-offset =
        #(grob-transformer 'Y-offset
          (lambda (grob orig)
            (let ((dir (ly:grob-property grob 'direction)))
              (+ orig (* dir half)))))
        \override Staff.OttavaBracket
          .outside-staff-padding = #(+ 0.46 half)
        \override Staff.OttavaBracket
          .extra-offset = #(lambda (grob)
            (let ((dir (ly:grob-property grob 'direction)))
              (cons 0 (* dir half))))
    #}
  ))

```

We can also verify that this new function still behaves properly when nearby grobs have pushed the `OttavaBracket` further than `Y-offset`.

Closing

In summary, we have produced a utility function that properly adjusts grob properties to shift an `OttavaBracket` away from the staff by a specified amount.

What are the next steps? First would be testing the function given real-world projects. These artificial scenarios could be hiding bad behavior. Second would be ensuring the function can cope with other adjustments. For instance, the function assumes that `OttavaBracket` will not have `outside-staff-padding` set, thus it can safely base its computation on the known default value.
